Processes and Threads

What are processes?

How does the operating system manage them?

Nick Urbanik

nicku@nicku.org

A computing department

Copyright Conditions: Open Publication License

(see <http://www.opencontent.org/openpub/>)

OSSI — ver. 1.5

Processeses - p. 1/112

What is a process?

- A **process** is a program in execution
- Each process has a **process ID**
- In Linux, `$ ps ax` prints one line for each process.
- A program can be executed a number of times simultaneously.
 - Each is a separate process.

OSSI — ver. 1.5

Processeses - p. 2/112

What is a process? — 2

- A process includes current values of:
 - Program counter
 - Registers
 - Variables
- A process also has:
 - The program code
 - It's own address space, independent of other processes
 - A user that owns it
 - A group owner
 - An **environment** and a **command line**
- This information is stored in a **process control block**, or **task descriptor** or **process descriptor**
 - a data structure in the OS, in the **process table**
 - See slides starting at §34.

OSSI — ver. 1.5

Processeses - p. 3/112

What is a thread?

- A *thread* is a lightweight process
 - Takes less CPU power to start, stop
- Part of a single process
- Shares address space with other threads in the same process
- Threads can share data more easily than processes
- Sharing data requires *synchronisation*, i.e., locking — see slide 95.
- This shared memory space can lead to complications in programming:

“Threads often prevent abstraction. In order to prevent deadlock, you often need to know how and if the library you are using uses threads in order to avoid deadlock problems. Similarly, the use of threads in a library could be affected by the use of threads at the application layer.” —

Dennis Korn

Processes - p. 4/112

See page 180, ESR in references, §112.

Environment of a process

- The *environment* is a set of names and values
- Examples:
PATH=/usr/bin:/bin:/usr/X11R6/bin
HOME=/home/nicku
SHELL=/bin/bash
- In Linux shell, can see environment by typing:
\$ **set**

Program counter

- The code of a process occupies memory
- The Program counter (PC) is a CPU register
- PC holds a memory address. . .
- . . . of the next instruction to be fetched and executed

OSSI — ver. 1.5

Processes - p. 5/112

Permissions of a Process

- A process executes with the permissions of its owner
 - The owner is the user that starts the process
- A Linux process can execute with permissions of another user or group
- If it executes as the owner of the program instead of the owner of the process, it is called *set user ID*
- Similarly for *set group ID* programs

Multitasking

- Our lab PCs have one main CPU
 - But multiprocessor machines are becoming increasingly common
 - Linux 2.6.x kernel scales to 16 CPUs
- How execute many processes “at the same time”?

OSSI — ver. 1.5

Processes - p. 8/112

Multitasking — 2

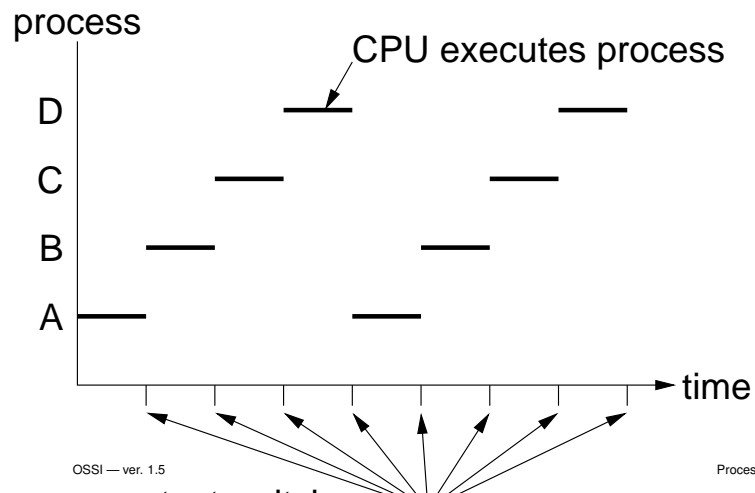

- CPU rapidly switches between processes that are “ready to run”
- Really: only one process runs at a time
- Change of process called a *context switch*
 - See slide §36
- With Linux: see how many context switches/second using `vmstat` under “system” in column “cs”

OSSI — ver. 1.5

Processes - p. 9/112

Multitasking — 3

- This diagram shows how the scheduler gives a “turn” on the CPU to each of four processes that are ready to run

Birth of a Process

- In Linux, a process is born from a `fork()` system call
 - A *system call* is a function call to an operating system service provided by the kernel
- Each process has a *parent*
- The parent process calls `fork()`
- The child inherits (*but cannot change*) the parent environment, open files
- Child is *identical* to parent, except for return value of `fork()`.
 - Parent gets child's process ID (PID)
 - Child gets 0

OSSI — ver. 1.5

Processes - p. 11/112

Process tree

- Processes may have parents and children
- Gives a family tree
- In Linux, see this with commands:
\$ **ps tree**
or
\$ **ps axf**

OSSI — ver. 1.5

Processes - p. 12/112

When to Switch Processes?

- The scheduler may change a process between **executing** (or **running**) and **ready to run** when any of these events happen:
 - clock interrupt
 - I/O interrupt
 - Memory fault
 - trap caused by error or exception
 - system call
- See slide §17 showing the **running** and **ready to run** process states.

OSSI — ver. 1.5

Processes - p. 14/112

Scheduler

- OS decides when to run each process that is ready to run (“runable”)
- The part of OS that decides this is the **scheduler**
- Scheduler aims to:
 - Maximise CPU usage
 - Maximise process completion
 - Minimise process execution time
 - Minimise waiting time for ready processes
 - Minimise response time

OSSI — ver. 1.5

Processes - p. 13/112

Scheduling statistics: vmstat

- The “system” columns give statistics about **scheduling**:
 - “cs” — number of context switches per second
 - “in” — number of interrupts per second
- See slide §36, `man vmstat`

OSSI — ver. 1.5

Processes - p. 15/112

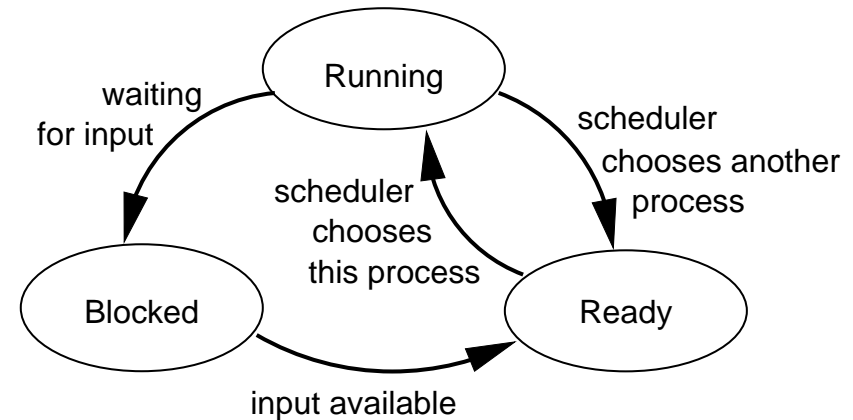

Interrupts

- Will discuss interrupts in more detail when we cover I/O
- An *interrupt* is an event (usually) caused by hardware that causes:
 - Saving some CPU registers
 - Execution of *interrupt handler*
 - Restoration of CPU registers
- An opportunity for scheduling

What is Most Common State?

- Now, my computer has 160 processes.
- How many are running, how many are ready to run, how many are blocked?
- What do you expect is most common state?

Process States

Most Processes are Blocked

```
9:41am up 44 days, 20:12, 1 user, load average: 2.02, 2.06, 2.13
160 processes: 145 sleeping, 2 running, 13 zombie, 0 stopped
```

- Here you see that most are sleeping, waiting for input!
- Most processes are "*I/O bound*"; they spend most time waiting for input or waiting for output to complete
- With one CPU, only one process can actually be running at one time
- However, surprisingly few processes are ready to run
- The *load average* is the average number of processes that are in the ready to run state.
- In output from the top program above, see over last 60 seconds, there are 2.02 processes on average in RTR state

Linux Process States

Linux Process States — 3

- **Stopped** — process is halted
 - can be restarted by another process
 - e.g., a debugger can put a process into stopped state
- **Zombie** — a process has terminated
 - but parent did not `wait()` for it (see slide 65)

Linux Process States — 2

- **Running** — actually contains two states:
 - *executing*, or
 - *ready to execute*
- **Interruptable** — a blocked state
 - waiting for event, such as:
 - end of an I/O operation,
 - availability of a resource, or
 - a signal from another process
- **Uninterruptable** — another blocked state
 - waiting directly on hardware conditions
 - will not accept any signals (even `SIGKILL`)

Process States: `vmstat`

- The “procs” columns give info about process states:
- “r” — number of processes that are in the *ready to run* state
- “b” — number of processes that are in the *uninterruptable* blocked state

Tools for monitoring processes

- Linux provides:
 - vmstat**
 - Good to monitor over time:
\$ `vmstat 5`
 - procinfo**
 - Easier to understand than `vmstat`
 - Monitor over time with
\$ `procinfo -f`
 - View processes with **top** — see slides 27 to §30
 - The system monitor **sar** shows data collected over time:
See `man sar`; investigate `sar -c` and `sar -q`
 - See the utilities in the `procps` software package. You can list them with
\$ `rpm -ql procps`

OSSI — ver. 1.5

Processes - p. 24/112

Monitoring processes in Win 2000

- Windows 2000 provides a tool:
 - Start → Administrative Tools → Performance.
 - Can use this to monitor various statistics

OSSI — ver. 1.5

Processes - p. 25/112

Process Monitoring with top

Process Monitoring — top

```
08:12:13 up 1 day, 13:34, 8 users, load average: 0.16, 0.24, 0.49
111 processes: 109 sleeping, 1 running, 1 zombie, 0 stopped
CPU states:  cpu  user  nice  system  irq  softirq  iowait  idle
              total  0.0%  0.0%   3.8%  0.0%   0.0%   0.0%  96.1%
Mem:  255608k av, 245064k used, 10544k free,      0k shrd, 17044k buff
      152460k active,          63236k inactive
Swap: 1024120k av, 144800k used, 879320k free          122560k cached
```

PID	USER	PRI	NI	SIZE	RSS	SHARE	STAT	%CPU	%MEM	TIME	CPU	COMMAND

OSSI — ver. 1.5

Processes - p. 26/112

OSSI — ver. 1.5

Processes - p. 27/112

top: load average

08:12:13 up 1 day, 13:34, 8 users, load average: 0.16, 0.24, 0.49

- **load average** is measured over the last minute, five minutes, fifteen minutes
- Over that time is the average number of processes that are **ready to run**, but which are **not executing**
- A measure of how “busy” a computer is.

OSSI — ver. 1.5

Processes - p. 28/112

top: Processes and Memory

PID	USER	PRI	NI	SIZE	RSS	SHARE	STAT	%CPU	%MEM	TIME	CPU	COMMAND
1253	root	15	0	73996	13M	11108	S	2.9	5.5	19:09	0	X

SIZE This column is the total size of the process, including the part which is swapped (paged out) out to the swap partition or swap file

Here we see that the process X uses a total of 73,996 Kb, i.e., $73,996 \times 1024 \text{ bytes} \approx 72\text{MB}$, where here $1\text{MB} = 2^{20} \text{ bytes}$.

RSS The **resident set size** is the total amount of RAM that a process uses, including memory shared with other processes. Here X uses a total of 13MB RAM, including RAM shared with other processes.

SHARE The amount of **shared** memory is the amount of RAM that this process shares with other processes. Here X shares 11,108 KB with other processes.

OSSI — ver. 1.5

Processes - p. 30/112

top: process states

111 processes: 109 sleeping, 1 running, 1 zombie, 0 stopped

sleeping Most processes (109/111) are sleeping, waiting for I/O

running This is the number of processes that are both ready to run and are executing

zombie There is one process here that has terminated, but its parent did not `wait()` for it.

- The `wait()` system calls are made by a parent process, to get the `exit()` status of its child(ren).
- This call removes the **process control block** from the **process table**, and the child process does not exist any more. (§34)

stopped When you press **Control-z** in a shell, you will increase this number by 1

Processes - p. 29/112

Virtual Memory: suspended processes

- With memory fully occupied by processes, could have all in blocked state!
- CPU could be completely idle, but other processes waiting for RAM
- Solution: **virtual memory**
 - will discuss details of VM in memory management lecture
- Part or all of process may be saved to swap partition or swap file

OSSI — ver. 1.5

Processes - p. 31/112

Suspended Processes

- Could add more states to process state table:
 - ready and suspended
 - blocked and suspended

OSSI — ver. 1.5

Processes - p. 32/112

Process Control Blocks

The Process Table

Data structure in OS to hold information about a process

OSSI — ver. 1.5

Processes - p. 33/112

OS Process Control Structures

- Every OS provides *process tables* to manage processes
- In this table, the entries are called *process control blocks* (PCBs), *process descriptors* or *task descriptors*. We will use the abbreviation PCB.
- There is one PCB for each process
- in Linux, PCB is called `task_struct`, defined in `include/linux/sched.h`
 - In a Fedora Core or Red Hat system, you will find it in the file `/usr/src/linux-2.*/include/linux/sched.h` if you have installed the `kernel-source` software package

OSSI — ver. 1.5

Processes - p. 34/112

What is in a PCB

- In slide §3, we saw that a PCB contains:
 - a process ID (PID)
 - *process state* (i.e., executing, ready to run, sleeping waiting for input, stopped, zombie)
 - *program counter*, the CPU register that holds the address of the next instruction to be fetched and executed
 - The value of other *CPU registers* the last time the program was switched out of executing by a *context switch* — see slide §36
 - scheduling priority
 - the *user* that owns the process
 - the *group* that owns the process
 - pointers to the *parent process*, and *child processes*
 - Location of *process's data* and *program code* in memory
 - List of *allocated resources* (including open files)

OSSI — ver. 1.5

Processes - p. 35/112

Context Switch

- OS does a *context switch* when:
 - stop current process from executing, and
 - start the next *ready to run* process executing on CPU
- OS saves the *execution context* (see §37) to its PCB
- OS loads the ready process's execution context from its PCB
- *When* does a context switch occur?
 - When a process *blocks*, i.e., goes to sleep, waiting for input or output (I/O), or
 - When the scheduler decides the process has had its turn of the CPU, and it's time to schedule another ready-to-run process
- A context switch must be as *fast as possible*, or multitasking will be too slow
 - Very fast in Linux OS

Program Counter in PCB

- What value is in the program counter in the PCB?
- If it is *not* executing on the CPU,
 - The *address of the next CPU instruction* that *will be* fetched and executed the next time the program starts executing
- If it *is* executing on the CPU,
 - The *address of the first CPU instruction* that *was* fetched and executed when the process began executing at the last context switch (§36)

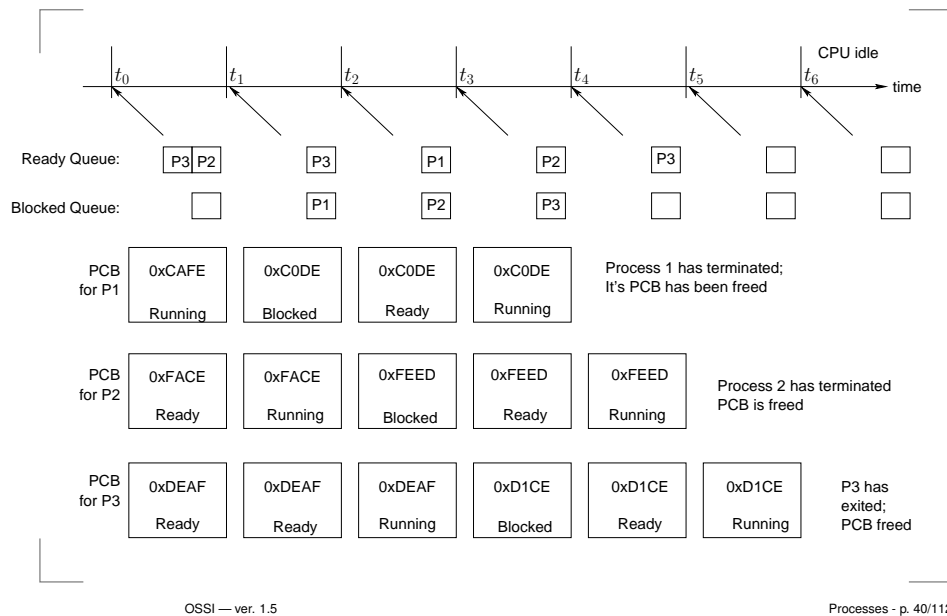

Execution Context

- Also called *state of the process* (but since this term has two meanings, we avoid that term here), *process context* or just *context*
- The *execution context* is all the data that the OS must *save* to stop one process from executing on a CPU, and *load* to start the next process running on a CPU
- This includes the content of all the CPU registers, the location of the code, . . .
 - Includes most of the contents of the process's PCB.

Process Control Blocks—Example

- The diagram in slide §40 shows three processes and their process control blocks.
- There are seven snapshots $t_0, t_1, t_2, t_3, t_4, t_5$ and t_6 at which the scheduler has changed process (there has been a context switch—§36)
- On this particular example CPU, all I/O instructions are 2 bytes long
- The diagram also shows the queue of processes in the:
 - *Ready queue* (processes that are ready to run, but do not have a CPU to execute on yet)
 - *Blocked*, or *Wait queue*, where the processes have been blocked because they are waiting for I/O to finish.

PCB Example: Diagram

PCB Example — Continued

- In slide §40,
 - The times $t_0, t_1, t_2, t_3, t_4, t_5$ and t_6 are when the scheduler has selected another process to run.
 - Note that these time intervals are *not equal*, they are just the points at which a scheduling change has occurred.
- Each process has stopped at one stage to perform I/O
 - That is why each one is put on the *wait queue* once during its execution.
- Each process has performed I/O once

OSSI — ver. 1.5

Processes - p. 41/112

What is the address of I/O instructions?

- We are given that all I/O instructions *in this particular example* are *two bytes* long (slide §39)
 - We can see that when the process is sleeping (i.e., blocked), then the program counter points to the instruction *after* the I/O instruction
 - So for process P1, which blocks with program counter $PC = C0DE_{16}$, the I/O instruction is at address $C0DE_{16} - 2 = C0DC_{16}$
 - for process P2, which blocks with program counter $PC = FEED_{16}$, the I/O instruction is at address $FEED_{16} - 2 = FEED_{16}$
 - for process P3, which blocks with program counter $PC = D1CE_{16}$, the I/O instruction is at address $D1CE_{16} - 2 = D1CC_{16}$

OSSI — ver. 1.5

Processes - p. 42/112

Process System Calls

How the OS controls processes

How you use the OS to control process

OSSI — ver. 1.5

Processes - p. 43/112

Major process Control System Calls

- `fork()` — start a new process
- `execve()` — replace calling process with machine code from another program file
- `wait()`, `waitpid()` — parent process gets status of its' child after the child has terminated, and cleans up the process table entry for the child (stops it being a *zombie*)
- `exit()` — terminate the current process

OSSI — ver. 1.5

Processes - p. 44/112

Process IDs and `init`

- Every process has a process ID (PID)
- process 0 is the scheduler, part of kernel
- process 1 is `init`, the parent of *all other processes*
 - a normal user process, not part of kernel
 - program file is `/sbin/init`
- All other processes result from `init` calling the `fork()` system call
- This is the *only* way a new process is created by the kernel

OSSI — ver. 1.5

Processes - p. 46/112

File I/O system calls: a sidetrack

```
#include <unistd.h>
```

```
ssize_t read( int filedes, void *buf,  
             size_t nbytes );
```

- returns number of bytes read, 0 at end of file, -1 on error
- `write(int filedes, void *buf, size_t nbytes);`
- returns number of bytes written, else -1 on error
- Note: these are *unbuffered*, that is, they have effect “immediately”.
- This is different from `stdio.h` functions, which are buffered for efficiency.

OSSI — ver. 1.5

Processes - p. 45/112

SUID, SGID and IDs

- Every process has *six* or more IDs associated with it
- UID and GID of person who executes program file:
 - real user ID, real group ID
- IDs used to calculate permissions:
 - Effective UID, Effective GID
- IDs saved when use `exec()` system call:
 - Saved set-user-ID, saved set-group-ID
 - idea is can drop special privileges and return to executing with real UID and real GID when privilege is no longer required

OSSI — ver. 1.5

Processes - p. 47/112

Other system calls: getting process info

```
#include <sys/types.h>
#include <unistd.h>
● pid_t getpid(void); returns PID of calling process
● pid_t getppid(void); returns PID of parent
● uid_t getuid(void); returns real user ID of process
● uid_t geteuid(void); returns effective user ID of process
● gid_t getgid(void); returns real group ID of process
● gid_t getegid(void); returns effective group ID of process
```

OSSI — ver. 1.5

Processes - p. 48/112

Using fork () : pseudocode

```
if ( ( pid = fork() ) < 0 )
    fork_error has happened
else if ( pid == 0 )
    /* I am the child */
    do things the child process should do
else
    /* I am the parent */
    do things the parent should do
```

OSSI — ver. 1.5

Processes - p. 50/112

fork () : what it does

```
#include <sys/types.h>
#include <unistd.h>
pid_t fork(void);
● returns 0 in child
● returns PID of child in parent
● returns -1 if error
```

OSSI — ver. 1.5

Processes - p. 49/112

Simple fork () Example (no Checking)

```
#include <stdio.h>
#include <unistd.h>

int main()
{
    int pid = fork();
    printf( "PID is %d\n", pid );
    if ( pid == 0 )
        printf( "I'm the child\n" );
    else
        printf( "I'm the parent\n" );
}
```

OSSI — ver. 1.5

Processes - p. 51/112

An example using fork ()

```
#include <sys/types.h>
#include <unistd.h>
#include <stdio.h>
int glob = 6;
char buf[] = "a write to standard output\n";
int main( void )
{
    int var = 88;                               /* local variable on the stack */
    pid_t pid;
    if ( write( STDOUT_FILENO, buf, sizeof (buf) - 1 )
        ≠ sizeof (buf) - 1 ) {
        fprintf( stderr, "write error" );
        exit( 1 );
    }
}
```

OSSI — ver. 1.5

Processes - p. 52/112

Output of fork-example.c:

```
$ gcc -o fork-example fork-example.c
$ ./fork-example
a write to standard output
before fork
pid = 7118, global = 7, var = 89 child's vars changed
pid = 7117, global = 6, var = 88 parent's copy not changed
```

OSSI — ver. 1.5

Processes - p. 54/112

Example using fork () —(contd.)

```
printf( "before fork\n" );
if ( ( pid = fork() ) < 0 ) {
    fprintf( stderr, "fork error\n" );
    exit( 1 );
} else if ( pid == 0 ) {                          /* child */
    ++glob;
    ++var;
} else
    sleep( 2 ); /* parent */
printf( "pid = %d, glob = %d, var = %d\n",
        getpid(), glob, var );
exit( 0 );
}
```

OSSI — ver. 1.5

Processes - p. 53/112

Running fork-example again

```
$ ./fork-example > tmp.out
$ cat tmp.out
a write to standard output
before fork
pid = 7156, global = 7, var = 89
before fork
pid = 7155, global = 6, var = 88
```

OSSI — ver. 1.5

Processes - p. 55/112

Why two “before fork” messages?

- `write()` system call not buffered
- `write()` called before `fork()`, so one output
- `printf()` is buffered
 - line buffered if connected to terminal
 - fully buffered otherwise; parent and child both have a copy of the unwritten buffer when redirected
- `exit()` causes both parent and child buffers to flush

OSSI — ver. 1.5

Processes - p. 56/112

Running another program — `exec()`

- To run another program file
- first call `fork()` to create a child process
- child calls `exec()` to replace current copy of parent with a totally new program in execution

OSSI — ver. 1.5

Processes - p. 58/112

So what does this show?

- It shows that the child is an exact copy of the parent, with all
 - variable values,
 - buffers,
 - open files,...
- All are inherited by the child

OSSI — ver. 1.5

Processes - p. 57/112

`execve()` system call

```
#include <unistd.h>
int execve( const char *filename,
            char *const argv[],
            char *const envp[] );
```

- executes the program `filename`, replaces current process
- Passes the command line in `argv[]`
- passes the environment variables in `envp[]`
- Does not return, unless error, when returns with `-1`
- Usually called through library `exec*()` calls — see man 3 `exec`

OSSI — ver. 1.5

Processes - p. 59/112

fork () — exec () Example

```
#include <stdio.h>
#include <unistd.h>

int main()
{
    int pid = fork();
    printf( "PID is %d\n", pid );
    if ( pid == 0 )
        printf( "I'm the child\n" );
    else
        printf( "I'm the parent\n" );
}
```

OSSI — ver. 1.5

Processes - p. 60/112

print .c: a program we call

```
#include <stdio.h>
#include <stdlib.h>

int main( int argc, char *argv[] )
{
    // argv[0] is the program name
    int num = atoi( argv[1] );
    int loops = atoi( argv[2] );
    int i;
    for ( i = 0; i < loops; ++i )
        printf( "%d ", num );
}
```

OSSI — ver. 1.5

Processes - p. 62/112

Using execl ()

```
int execl( const char *path,
           const char *arg, ... );
```

- Parameter number:
 1. gives full path of the program file you want to execute
 2. gives name of the new process
 3. specifies the command line arguments you pass to the program
 4. last is a NULL pointer to end the parameter list.
- We must always put a NULL pointer at the end of this list.

OSSI — ver. 1.5

Processes - p. 61/112

Calling ./print using execl ()

```
#include <stdio.h>
#include <unistd.h>

int main()
{
    printf( "hello world\n" );
    int pid = fork();
    printf( "fork returned %d\n", pid );
    if ( pid == 0 )
        execl( "./print", "print", "1", "100", NULL );
    else
        execl( "./print", "print", "2", "100", NULL );
}
```

OSSI — ver. 1.5

Processes - p. 63/112

vfork () system call

- A lightweight `fork()`
- Designed for running `execvp()` straight after
 - modern Linux `fork()` is very efficient when call `exec*()`
- Child does not contain an exact copy of parent address space;
- child calls `exec()` or `exit()` after `fork()`
- parent is suspended till child calls `fork()` or `exit()`

OSSI — ver. 1.5

Processes - p. 64/112

wait (), waitpid () system calls

- `wait()` can block caller until child process terminates
- `waitpid()` has option to prevent blocking
- `waitpid()` can wait for a specific child instead of the first child
- if child has terminated already (it's a *zombie*), `wait` returns immediately, cleaning up the process table data structures for the child

OSSI — ver. 1.5

Processes - p. 66/112

wait (), waitpid () system calls

```
#include <sys/types.h>
#include <sys/wait.h>

pid_t wait( int *status );

pid_t waitpid( pid_t pid,
               int *status,
               int options );
```

- return process ID if OK, 0, or -1 on error

OSSI — ver. 1.5

Processes - p. 65/112

Part of Simple Shell Program

```
int main( int argc, char **argv )
{
    char *prog_name = basename( *argv );
    print_prompt( prog_name );
    read_command();
    for ( ;; ) {
        int pid = fork();
        if ( pid == 0 ) {
            execvp( args[ 0 ], args );
        }
        wait( NULL );
        print_prompt( prog_name );
        read_command();
    }
}
```

OSSI — ver. 1.5

Processes - p. 67/112

Windows and Processes

- Windows provides a Win32 API call to create a process:
`CreateProcess()`
- Creates a new process, loads program into that process
- `CreateProcess()` takes *ten* parameters

OSSI — ver. 1.5

Processes - p. 68/112

CreateProcess () prototype

- `CreateProcess()` is *much* more complicated than
`pid_t fork(void);`
- Four of the parameters point to `structs`, e.g.,
 - `LPSTARTUPINFO` points to a `struct` with 4 members
 - `LPPROCESS_INFORMATION` points to a `struct` with 18 members!

```
BOOL CreateProcess (  
    LPCTSTR lpApplicationName, // pointer to executable module  
    LPTSTR lpCommandLine, // pointer to command line string  
    LPSECURITY_ATTRIBUTES lpProcessAttrib, // process security  
    LPSECURITY_ATTRIBUTES lpThreadAttrib, // thread security  
    BOOL bInheritHandles, // handle inheritance flag  
    DWORD dwCreationFlags, // creation flags  
    LPVOID lpEnvironment, // pointer to new environment block  
    LPCTSTR lpCurrentDirectory, // pointer to current dir name
```

OSSI — ver. 1.5

Processes - p. 70/112

Windows and Processes — 2

- Win32 uses *handles* for almost all objects such as files, pipes, sockets, processes and events
- handles can be inherited from parent
- No proper parent-child relationship
 - caller of `CreateProcess()` could be considered as parent
 - but child cannot determine it's parent

OSSI — ver. 1.5

Processes - p. 69/112

CreateProcess ()

- Can Specify Program in either 1st or 2nd parameter:
 - first: location of program to execute
 - second: command line to execute
- Creation flags:
 - if 0, runs in existing window

OSSI — ver. 1.5

Processes - p. 71/112

Example: CreateProcess ()

```
#include <windows.h>
#include <stdio.h>

void main() {
    STARTUPINFO si;
    PROCESS_INFORMATION pi;
    memset( &si, 0, sizeof( si ) );
    si.cb = sizeof(si);
    if ( ! CreateProcess( NULL,
        "..\\..\\print\\Debug\\print.exe 5 100",
        NULL, NULL, TRUE, 0, NULL, NULL, &si, &pi ) )
        fprintf( stderr, "CreateProcess failed with %d\n", GetLastError() );
    WaitForSingleObject( pi.hProcess, INFINITE );
    CloseHandle( pi.hProcess );
    CloseHandle( pi.hThread );
}
```

OSSI — ver. 1.5

Processes - p. 72/112

Processes in Linux, Unix, Windows

- Linux often provides 2 or more processes per application
- Example: apache web server parent process watches for connections, one child process per client
- Linux processes have much less overhead than in Windows
- `fork ()` — `exec ()` very efficient
- POSIX threads are very efficient, and faster than `fork ()` — `exec ()`
- Windows have one process per application, but often 2 or more threads
- Windows `CreateProcess ()` takes more time than `fork ()` — `exec ()`
- `CreateThread ()` takes very much less time than `CreateProcess ()`

OSSI — ver. 1.5

Processes - p. 73/112

Problem with Processes

- Communication!
- Processes cannot see the same variables
- Must use *Inter Process Communication* (IPC)
- IPC Techniques include:
 - pipes, and named pipes (FIFOs)
 - sockets
 - messages and message queues
 - shared memory regions
- All have some overhead

OSSI — ver. 1.5

Processes - p. 75/112

IPC

Inter Process Communication

How Processes can Talk to Each Other

OSSI — ver. 1.5

Processes - p. 74/112

Interprocess Communication (IPC)

- **Pipe** — circular buffer, can be written by one process, read by another
 - related processes can use unnamed pipes
 - used in **shell programming**, e.g., the vertical bar '|' in
`$ find /etc | xargs file`
 - unrelated processes can use **named pipes** — sometimes called **FIFOs**
- **Messages** — POSIX provides system calls `msgsnd()` and `msgrcv()`
 - message is block of text with a type
 - each process has a message queue, like a mailbox
 - processes are suspended when attempt to read from empty queue, or write to full queue.

OSSI — ver. 1.5

Processes - p. 76/112

IPC — Signals

- Some **signals** can be generated from the keyboard, i.e.,
`Control-C` — interrupt (`SIGINT`); `Control-\` — quit (`SIGQUIT`), `Control-Z` — stop (`SIGSTOP`)
- A process **sends a signal** to another process using the **kill()** system call
- signals are implemented as single bits in a field in the PCB, so cannot be queued
- A process may respond to a signal with:
 - a **default action** (usually process terminates)
 - a **signal handler** function (see **trap** in shell programming notes), or
 - ignore the signal (unless it is `SIGKILL` or `SIGSTOP`)
- A process **cannot ignore**, or handle a `SIGSTOP` or a `SIGKILL` signal.
 - A **KILL** signal will **always terminate** a process (unless it is in interruptible sleep)

OSSI — ver. 1.5

Processes - p. 78/112

IPC — Shared Memory

- **Shared Memory** — a Common block of memory shared by many processes
- Fastest way of communicating
- Requires synchronisation (See slide 95)

OSSI — ver. 1.5

Processes - p. 77/112

Signals and the Shell

- We can use the **kill** built in command to make the **kill()** system call to **send** a signal
- A shell script uses the **trap** built in command to **handle** a signal
- **Ignoring** the signals `SIGINT`, `SIGQUIT` and `SIGTERM`:

```
trap "" INT QUIT TERM
```
- **Handling** the same signals by printing a message then exiting:

```
trap "echo 'Got a signal; exiting.';exit 1" INT QUIT TERM
```
- Handling the same signals with a function call:

```
signal_handler() {
    echo "Received a signal; terminating."
    rm -f $temp_file
    exit 1
}
trap signal_handler INT QUIT TERM
```

OSSI — ver. 1.5

Processes - p. 79/112

Threads and Processes

Threads

Lightweight processes that can talk to each other easily

- Threads in a process all share the same address space
- Communication easier
- Overhead less
- Problems of *locking* and *deadlock* a major issue
- Processes have separate address spaces
- Communication more indirect: IPC (Inter Process Communication)
- Overhead higher
- Less problem with shared resources (since fewer resources to share!)

OSSI — ver. 1.5

Processes - p. 80/112

OSSI — ver. 1.5

Processes - p. 81/112

Threads have own...

- stack pointer
- register values
- scheduling properties, such as policy or priority
- set of signals they can each block or receive
- own stack data (local variables are local to thread)

OSSI — ver. 1.5

Processes - p. 82/112

Threads share a lot

- Changes made by one thread to shared system resources (such as closing a file) will be seen by all other threads.
- Two pointers having the same value point to the same data.
- A number of threads can read and write to the same memory locations, and so you need to explicitly *synchronise* access

OSSI — ver. 1.5

Processes - p. 83/112

Threads in Linux, Unix

- POSIX is a standard for Unix
- Linux implements POSIX threads
- On Red Hat 8.x, documentation is at
 - \$ **info '(libc) POSIX Threads'**
 - or in Emacs, C-H m libc then middle-click on POSIX threads
- Provides:
 - *semaphores*,
 - *mutexes* and
 - *condition variables*for locking (synchronisation)

OSSI — ver. 1.5

Processes - p. 84/112

hello.c: a simple threaded program

```
#include <pthread.h>
#include <stdio.h>
#define NUM_THREADS 5
void * print_hello( void *threadid )
{
    printf( "\n%d: Hello World!\n", threadid );
    pthread_exit( NULL );
}
int main()
{
    pthread_t threads[ NUM_THREADS ];
    int rc, t;
    for ( t= 0; t < NUM_THREADS; t++ ) {
        printf( "Creating thread %d\n", t );
        rc = pthread_create( &threads[ t ], NULL, print_hello, ( void * ) t );
        if ( rc ) { printf( "ERROR; pthread_create() returned %d\n", rc );
                      exit( -1 );
        }
    }
    pthread_exit( NULL );
}
```

OSSI — ver. 1.5

Processes - p. 85/112

How to Compile a POSIX Threads Program

- Need to use the `libpthread` library
 - Specify this with the option `-lpthread`
- Need to tell the other libraries that they should be *reentrant* (or "*thread safe*")
 - This means that the library uses no static variables that may be overwritten by another thread
 - Specify this with the option `-D_REENTRANT`
- So, to compile the program `<program>.c`, do:
 - \$ `gcc -D_REENTRANT -lpthread -o <program> <program>.c`

OSSI — ver. 1.5

Processes - p. 86/112

pthread_create ()

```
#include <pthread.h>

void *
pthread_create( pthread_t *thread,
               pthread_attr_t *attr,
               void * (*start_routine)( void * ),
               void *arg );
```

- returns: 0 if successfully creates thread
- returns error code otherwise

OSSI — ver. 1.5

Processes - p. 87/112

pthread_create ()

- Quite different from `fork()`
- Thread must always execute a *user-defined function*
- parameters:
 1. pointer to thread identifier
 2. attributes for thread, including stack size
 3. user function to execute
 4. parameter passed to the user function

Problem with threads:

- Avoid 2 or more threads writing or reading and writing same data at the same time
- Avoid *data corruption*
- Need to control access to data, devices, files
- Need *locking*
- Provide three methods of locking:
 - mutex (**mutual exclusion**)
 - semaphores
 - condition variables

Race Condition

Race Conditions

- *race condition* — where outcome of computation depends on scheduling
- an error in coding
- Example: two threads both access same list with code like this:

```
if ( list.numitems > 0 ) {  
    // Oh, dear, better not change to  
    // other thread here!  
    remove_item( list ); // not here!  
    // ...and not here either:  
    --list.numitems;  
}
```

Critical Sections

- **critical resource** — a device, file or piece of data that cannot be shared
- **critical section** — part of program only one thread or process should access **contains a critical resource**
 - i.e., you lock **data, not code**
- **All the code in the previous slide is a critical section**
- Consider the code:
`very_important_count++;`
- executed by two threads on a multiprocessor machine (SMP = **s**ymmetric **m**ultiprocessor)

OSSI — ver. 1.5

Processes - p. 92/112

Example — another possibility

thread 1	thread 2
<code>read very_important_count (5)</code>	
	<code>read very_important_count (5)</code>
<code>add 1 (6)</code>	
	<code>add 1 (6)</code>
<code>write very_important_count (6)</code>	
	<code>write very_important_count (6)</code>

OSSI — ver. 1.5

Processes - p. 94/112

Race Condition — one possibility

thread 1	thread 2
<code>read very_important_count (5)</code>	
<code>add 1 (6)</code>	
<code>write very_important_count (6)</code>	
	<code>read very_important_count (6)</code>
	<code>add 1 (7)</code>
	<code>write very_important_count (7)</code>

OSSI — ver. 1.5

Processes - p. 93/112

Solution: Synchronisation

- Solution is to **recognise critical sections**
- use **synchronisation**, i.e., locking, to make sure only one thread or process can enter critical region at one time.
- Methods of synchronisation include:
 - file locking
 - semaphores
 - monitors
 - spinlocks
 - mutexes

OSSI — ver. 1.5

Processes - p. 95/112

File Locking

- For example, an `flock()` system call can be used to provide *exclusive access* to an open file
- The call is *atomic*
 - It either:
 - completely succeeds in locking access to the file, or
 - it fails to lock access to the file, because another thread or process holds the lock
 - No “half-locked” state
 - *No race condition*
- Alternatives can result in race conditions; for example:
 - thread/process 1 checks lockfile
 - thread/process 2 checks lockfile a very short time later
 - both processes think they have exclusive write access to the file
 - file is corrupted by two threads/processes writing to it at the same time

Processes - p. 96/112

Synchronisation

- *Synchronisation* is a facility that enforces
 - mutual exclusion and
 - event ordering
- Required when multiple active processes or threads can access shared address spaces or shared I/O resources
- even more critical for SMP (*S*ymmetric *M*ulti*p*rocessor) systems
 - kernel can run on any processor
 - all processors are of equal importance (there is no one CPU that is the “boss”)
 - SMP systems include PCs with more than one CPU, as you might find in the Golden Shopping Centre

OSSI — ver. 1.5

Processes - p. 98/112

Methods of Synchronisation

What is it?

mutex, semaphore, condition variables, monitor, spinlock

OSSI — ver. 1.5

Processes - p. 97/112

Semaphores

- A variable with three operations:
 - *initialise* to non-negative value
 - *down* (or *wait*) operation:
 - decrement variable
 - if variable becomes negative, then process or thread executing the *down* operation is blocked
 - has nothing to do with the `wait` system call for a parent process to get status of its child
 - *up* (or *signal*) operation:
 - increment the semaphore variable;
 - if value is not positive, then a process or thread blocked by a *down* operation is unblocked.
- A semaphore also has a *queue* to hold processes or threads waiting on the semaphore.

OSSI — ver. 1.5

Processes - p. 99/112

Semaphores — 2

- The *up* and *down* semaphore operations are *atomic*
 - the *up* and *down* operations cannot be interrupted
 - each routine is a single, indivisible step
- Using semaphores—pseudocode

```
/* only one process can enter critical section at one time: */  
semaphore s = 1;
```

```
down( s );  
/* critical section */  
up( s );
```

- *Initialise* semaphore to *number of processes allowed into critical section at one time*

OSSI — ver. 1.5

Processes - p. 100/112

mutex — POSIX Threads Example (1)

- It is *good practice* to *put the mutex together with the data it protects*
- I have *removed the error checking* from this example to save space—in real code, *always check library calls for error conditions*

```
#include <pthread.h>  
#include <stdio.h>
```

```
struct {  
    pthread_mutex_t mutex; /* protects access to value */  
    int value;             /* Access protected by mutex */  
} data = { PTHREAD_MUTEX_INITIALIZER, 0 };
```

OSSI — ver. 1.5

Processes - p. 102/112

Mutex—POSIX and Win32 Threads

- *mutual exclusion*
- Easier to use than semaphores (see slide 99)
- When only one thread or process needs to write to a resource
 - all other writers refused access
- A *special form of the more general semaphore*
 - *Can have only two values*;
 - sometimes called *binary semaphores*.

OSSI — ver. 1.5

Processes - p. 101/112

mutex — POSIX Threads Example (2)

```
#define NUM_THREADS 5  
  
void *thread( void *t_id ) {  
    int i;  
    for ( i = 0; i < 200; ++i ) {  
        pthread_mutex_lock( &data.mutex );  
        ++data.value;  
        printf( "thread %d: data value = %d\n",  
              t_id, data.value );  
        pthread_mutex_unlock( &data.mutex );  
    }  
    pthread_exit( NULL );  
}
```

OSSI — ver. 1.5

Processes - p. 103/112

mutex — POSIX Threads Example (3)

```
int main() {
    pthread_t threads[ NUM_THREADS ];
    int rc, t;
    for ( t = 0; t < NUM_THREADS; t++ ) {
        printf( "Creating thread %d\n", t );
        pthread_create( &threads[ t ], NULL, thread,
                       ( void * ) t );
    }
    pthread_exit( NULL );
}
```

OSSI — ver. 1.5

Processes - p. 104/112

Monitors

- A *higher level structure for synchronisation*
- Implemented in Java, and some libraries
- main characteristics:
 - data in monitor is accessible only to procedures in monitor
 - a process or thread enters monitor by executing one of its procedures
 - Only one process or thread may be executing in the monitor at one time.
- Can implement with mutexes and condition variables.

OSSI — ver. 1.5

Processes - p. 106/112

POSIX Condition Variables

- Lets threads sleep till a condition about shared data is true
- Basic operations:
 - signal the condition (when condition is true)
 - wait for the condition
 - suspend the thread till another thread signals the condition
- Always associated with a mutex
- Very useful
- Missing from Windows: See <http://www.cs.wustl.edu/~schmidt/win32-cv-1.html>

OSSI — ver. 1.5

Processes - p. 105/112

Spinlocks

- Used in operating system kernels in SMP systems
- Linux uses kernel spinlocks only for SMP systems
- a very simple single-holder lock
- if can't get the spinlock, you keep trying (spinning) until you can.
- Spinlocks are:
 - very small and fast, and
 - can be used anywhere

OSSI — ver. 1.5

Processes - p. 107/112

Summary and References

Summary — Processes and Threads

- With Linux and Unix, main **process system calls** are **fork()**, **exec()** and **wait()** — understand the function of each of these
- Windows provides **CreateProcess()** and various **WaitFor...** Win32 API calls
 - The **WaitFor...** calls have a purpose similar to that of the **wait()** system call in Linux and Unix
- **Threads** are lightweight processes
 - part of one process
 - share address space
 - can share data easily
 - sharing data requires synchronisation, i.e., locking

Summary — Process States, Scheduling

- Scheduler changes processes between ready to run and running states
 - context switch: when scheduler changes process or thread
- Most processes are **blocked**, i.e., sleeping: waiting for I/O
 - understand the process states
 - why a process moves from one state to another
- Communication between processes is not trivial; **IPC** methods include
 - pipes
 - messages
 - shared memory
 - signals
 - semaphores

Summary — Synchronisation

- When two threads of execution can both write to same data or I/O,
 - Need enforce discipline
 - Use **synchronisation**
- We looked at the following methods of synchronisation:
 - semaphore
 - mutex
 - condition variable
 - monitor
 - spinlock
- There are other methods we have not examined here.

References

There are many good sources of information in the library and on the Web about processes and threads. Here are some I recommend:

- A **good online tutorial** about POSIX threads:
<http://www.llnl.gov/computing/tutorials/workshops/workshop/pthreads/MAIN.html>
- <http://www.humanfactor.com/pthreads/> provides links to a lot of information about POSIX threads
- The **best book** about POSIX threads is *Programming with POSIX Threads*, David Buten Hof, Addison-Wesley, May 1997. Even though it was written so long ago, David wrote much of the POSIX threads standard, so it really is the definitive work. It made me laugh, too!
- *Operating Systems: A Modern Perspective: Lab Update*, 2nd Edition, Gary Nutt, Addison-Wesley, 2002. A nice text book that emphasises the practical (like I do!)
- Microsoft MSDN provides details of Win32 API calls and provides examples of code.
- William Stallings, *Operating Systems*, Fourth Edition, Prentice Hall, 2001, chapters 3, 4 and 5
- Deitel, Deitel and Choffnes, *Operating Systems*, Third Edition, Prentice Hall, 2004, ISBN 0-13-118282-4, chapters 3, 4 and 5
- Paul Rusty Russell, *Unreliable Guide To Locking*
