

Processes and Threads

What are processes?

How does the operating system manage them?

Nick Urbanik

What is a process?

- A *process* is a program in execution
- Each process has a *process ID*
- In Linux,
\$ **ps ax**
- prints one line for each process.
- A program can be executed a number of times simultaneously.
 - ◆ Each is a separate process.

Summary and References

What is a process? — 2

- A process includes current values of:
 - ◆ Program counter
 - ◆ Registers
 - ◆ Variables
- A process also has:
 - ◆ The program code
 - ◆ It's own address space, independent of other processes
 - ◆ A user that owns it
 - ◆ A group owner
 - ◆ An *environment* and a *command line*
- This information is stored in a *process control block*, or *task descriptor* or *process descriptor*
 - ◆ a data structure in the OS, in the *process table*
 - ◆ See slides starting at §34.

[Summary and References](#)

What is a thread?

- A *thread* is a lightweight process
 - ◆ Takes less CPU power to start, stop
- Part of a single process
- Shares address space with other threads in the same process
- Threads can share data more easily than processes
- Sharing data requires *synchronisation*, i.e., locking — see slide 61.
- This shared memory space can lead to complications in programming:

“Threads often prevent abstraction. In order to prevent deadlock. you often need to know how and if the library you are using uses threads in order to avoid deadlock problems. Similarly, the use of threads in a library could be affected by the use of threads at the application layer.” — *David Korn*

See page 180, ESR in references, §66.

[Summary and References](#)

Program counter

- The code of a process occupies memory
- The Program counter (PC) is a CPU register
- PC holds a memory address. . .
- . . . of the next instruction to be fetched and executed

[Introduction](#)

[What is a process?](#)

Environment of a process

- The *environment* is a set of names and values
- Examples:
PATH=/usr/bin:/bin:/usr/X11R6/bin
HOME=/home/nicku
SHELL=/bin/bash
- In Linux shell, can see environment by typing:
\$ **set**

Permissions of a Process

- A process executes with the permissions of its owner
 - ◆ The owner is the user that starts the process
- A Linux process can execute with permissions of another user or group
- If it executes as the owner of the program instead of the owner of the process, it is called *set user ID*
- Similarly for *set group ID* programs

[Summary and References](#)

Multitasking — 2

- CPU rapidly switches between processes that are “ready to run”
- Really: only one process runs at a time
- Change of process called a *context switch*
 - ◆ See slide §36
- With Linux: see how many context switches/second using `vmstat` under “system” in column “cs”

[Summary and References](#)

Birth of a Process

- In Linux, a process is born from a `fork()` system call
 - ◆ A *system call* is a function call to an operating system service provided by the kernel
- Each process has a *parent*
- The parent process calls `fork()`
- The child inherits (*but cannot change*) the parent environment, open files
- Child is *identical* to parent, except for return value of `fork()`.
 - ◆ Parent gets child's process ID (PID)
 - ◆ Child gets 0

[Scheduler](#)

[Process States](#)

[top](#)

[Process Control Blocks](#)

[System Calls](#)

[IPC](#)

[Threads](#)

[Race Condition](#)

[Summary and References](#)

- OS decides when to run each process that is ready to run (“runable”)
- The part of OS that decides this is the *scheduler*
- Scheduler aims to:
 - ◆ Maximise CPU usage
 - ◆ Maximise process completion
 - ◆ Minimise process execution time
 - ◆ Minimise waiting time for ready processes
 - ◆ Minimise response time

[Process States](#)

[top](#)

[Process Control Blocks](#)

[System Calls](#)

[IPC](#)

[Threads](#)

[Race Condition](#)

[Summary and References](#)

When to Switch Processes?

- The scheduler may change a process between **executing** (or **running**) and **ready to run** when any of these events happen:
 - ◆ clock interrupt
 - ◆ I/O interrupt
 - ◆ Memory fault
 - ◆ trap caused by error or exception
 - ◆ system call
- See slide §17 showing the **running** and **ready to run** process states.

[IPC](#)

[Threads](#)

[Race Condition](#)

[Summary and References](#)

Interrupts

- Will discuss interrupts in more detail when we cover I/O
- An *interrupt* is an event (usually) caused by hardware that causes:
 - ◆ Saving some CPU registers
 - ◆ Execution of *interrupt handler*
 - ◆ Restoration of CPU registers
- An opportunity for scheduling

[top](#)

[Process Control Blocks](#)

[System Calls](#)

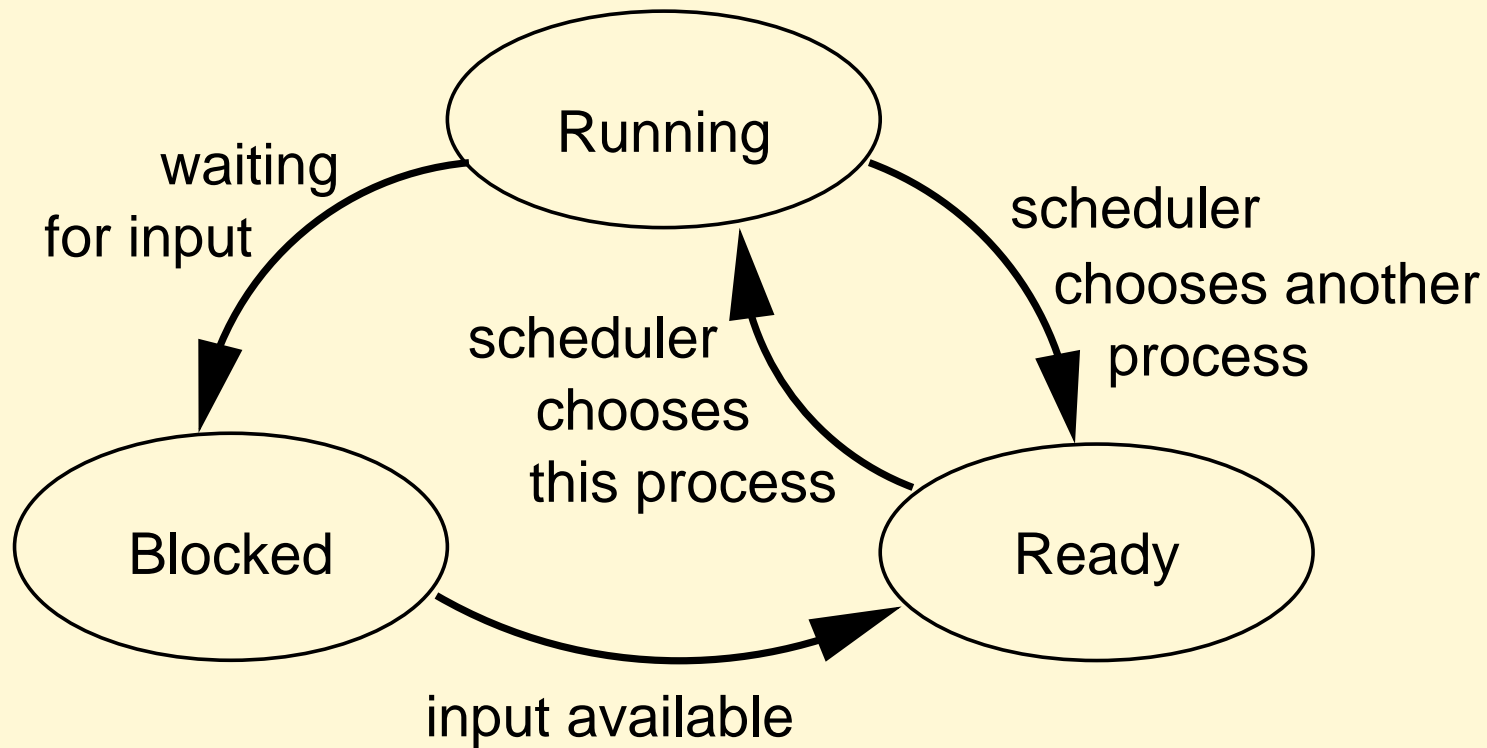

[IPC](#)

[Threads](#)

[Race Condition](#)

[Summary and References](#)

Most Processes are Blocked

```
9:41am up 44 days, 20:12, 1 user, load average: 2.02, 2.06, 2.13
160 processes: 145 sleeping, 2 running, 13 zombie, 0 stopped
```

- Here you see that most are sleeping, waiting for input!
- Most processes are “*I/O bound*”; they spend most time waiting for input or waiting for output to complete
- With one CPU, only one process can actually be running at one time
- However, surprisingly few processes are ready to run
- The *load average* is the average number of processes that are in the ready to run state.
- In output from the top program above, see over last 60 seconds, there are 2.02 processes on average in RTR state

Linux Process States — 2

- **Running** — actually contains two states:
 - ◆ *executing*, or
 - ◆ *ready to execute*
- **Interruptable** — a blocked state
 - ◆ waiting for event, such as:
 - end of an I/O operation,
 - availability of a resource, or
 - a signal from another process
- **Uninterruptable** — another blocked state
 - ◆ waiting directly on hardware conditions
 - ◆ will not accept any signals (even `SIGKILL`)

Tools for monitoring processes

- Linux provides:
- **vmstat**
 - ◆ Good to monitor over time:
\$ **vmstat 5**
- **procinfo**
 - ◆ Easier to understand than `vmstat`
 - ◆ Monitor over time with
\$ **procinfo -f**
- View processes with **top** — see slides 27 to §30
- The system monitor **sar** shows data collected over time:
See `man sar`; investigate `sar -c` and `sar -q`
- See the utilities in the `procps` software package. You can list them with
\$ **rpm -ql procps**

[Summary and References](#)

top: process states

111 processes: 109 sleeping, 1 running, 1 zombie, 0 stopped

sleeping Most processes (109/111) are sleeping, waiting for I/O

running This is the number of processes that are both ready to run and are executing

zombie There is one process here that has terminated, but its parent did not `wait()` for it.

- The `wait()` system calls are made by a parent process, to get the `exit()` status of its child(ren).
- This call removes the *process control block* from the *process table*, and the child process does not exist any more. (§34)

stopped When you press **Control-z** in a shell, you will increase this number by 1

PID	USER	PRI	NI	SIZE	RSS	SHARE	STAT	%CPU	%MEM	TIME	CPU	COMMAND
1253	root	15	0	73996	13M	11108	S	2.9	5.5	19:09	0	X

SIZE This column is the total size of the process, including the part which is swapped (paged out) out to the swap partition or swap file

Here we see that the process X uses a total of 73,996 Kb, i.e., $73,996 \times 1024 \text{ bytes} \approx 72\text{MB}$, where here $1\text{MB} = 2^{20}$ bytes.

RSS The *resident set size* is the total amount of RAM that a process uses, including memory shared with other processes. Here X uses a total of 13MB RAM, including RAM shared with other processes.

SHARE The amount of *shared* memory is the amount of RAM that this process shares with other processes. Here X shares 11,108 KB with other processes.

We can see that the total amount of RAM used exclusively by one process is $\text{rss} - \text{share}$. Here we see that X uses about $13 \times 2^{20} - 11,108 \times 2^{10} \approx 2 \text{MB}$

OS Process Control Structures

- Every OS provides *process tables* to manage processes
- In this table, the entries are called *process control blocks* (PCBs), *process descriptors* or *task descriptors*. We will use the abbreviation PCB.
- There is one PCB for each process
- in Linux, PCB is called `task_struct`, defined in `include/linux/sched.h`
 - ◆ In a Fedora Core or Red Hat system, you will find it in the file `/usr/src/linux-2.*/include/linux/sched.h` if you have installed the `kernel-source` software package

What is in a PCB

- In slide §3, we saw that a **PCB** contains:
 - ◆ a process ID (**PID**)
 - ◆ **process state** (i.e., executing, ready to run, sleeping waiting for input, stopped, zombie)
 - ◆ **program counter**, the CPU register that holds the address of the next instruction to be fetched and executed
 - ◆ The value of other **CPU registers** the last time the program was switched out of executing by a **context switch** — see slide §36
 - ◆ scheduling priority
 - ◆ the **user** that owns the process
 - ◆ the **group** that owns the process
 - ◆ pointers to the **parent process**, and **child processes**
 - ◆ Location of **process's data** and **program code** in memory
 - ◆ List of **allocated resources** (including open **files**)
- PCB holds the **values as they were when process was last switched out of executing by a context switch** — see slide §36

Context Switch

- OS does a *context switch* when:
 - ◆ stop current process from executing, and
 - ◆ start the next *ready to run* process executing on CPU
- OS saves the *execution context* (see §37) to its PCB
- OS loads the ready process's execution context from its PCB
- *When* does a context switch occur?
 - ◆ When a process *blocks*, i.e., goes to sleep, waiting for input or output (I/O), or
 - ◆ When the scheduler decides the process has had its turn of the CPU, and it's time to schedule another ready-to-run process
- A context switch must be as *fast as possible*, or multitasking will be too slow
 - ◆ Very fast in Linux OS

Execution Context

- Also called *state of the process* (but since this term has two meanings, we avoid that term here), *process context* or just *context*
- The *execution context* is all the data that the OS must **save** to stop one process from executing on a CPU, and **load** to start the next process running on a CPU
- This includes the content of all the CPU registers, the location of the code, . . .
 - ◆ Includes most of the contents of the process's PCB.

Program Counter in PCB

- What value is in the program counter in the PCB?
- If it is *not* executing on the CPU,
 - ◆ The **address of the next CPU instruction** that *will be* fetched and executed the next time the program starts executing
- If it *is* executing on the CPU,
 - ◆ The **address of the first CPU instruction** that *was* fetched and executed when the process began executing at the last context switch (§36)

Process Control Blocks—Example

- The diagram in slide §40 shows three processes and their process control blocks.
- There are seven snapshots $t_0, t_1, t_2, t_3, t_4, t_5$ and t_6 at which the scheduler has changed process (there has been a context switch—§36)
- On this particular example CPU, all I/O instructions are 2 bytes long
- The diagram also shows the queue of processes in the:
 - ◆ *Ready queue* (processes that are ready to run, but do not have a CPU to execute on yet)
 - ◆ *Blocked*, or *Wait queue*, where the processes have been blocked because they are waiting for I/O to finish.

PCB Example: Diagram

PCB Example — Continued

- In slide §40,
 - ◆ The times $t_0, t_1, t_2, t_3, t_4, t_5$ and t_6 are when the scheduler has selected another process to run.
 - ◆ Note that these time intervals are *not equal*, they are just the points at which a scheduling change has occurred.
- Each process has stopped at one stage to perform I/O
 - ◆ That is why each one is put on the *wait queue* once during its execution.
- Each process has performed I/O once

[IPC](#)

[Threads](#)

[Race Condition](#)

[Summary and References](#)

What is the address of I/O instructions?

- We are given that all I/O instructions *in this particular example* are **two bytes** long (slide §39)
 - ◆ We can see that when the process is sleeping (i.e., blocked), then the program counter points to the instruction *after* the I/O instruction
 - ◆ So for process P1, which blocks with program counter $PC = C0DE_{16}$, the I/O instruction is at address $C0DE_{16} - 2 = C0DC_{16}$
 - ◆ for process P2, which blocks with program counter $PC = FEED_{16}$, the I/O instruction is at address $FEED_{16} - 2 = FEEB_{16}$
 - ◆ for process P3, which blocks with program counter $PC = D1CE_{16}$, the I/O instruction is at address $D1CE_{16} - 2 = D1CC_{16}$

[Summary and References](#)

Major process Control System Calls

- **fork()** — start a new process
- **execve()** — replace calling process with machine code from another program file
- **wait()**, **waitpid()** — parent process gets status of its' child after the child has terminated, and cleans up the process table entry for the child (stops it being a *zombie*)
- **exit()** — terminate the current process

Problem with Processes

- Communication!
- Processes cannot see the same variables
- Must use *Inter Process Communication* (IPC)
- IPC Techniques include:
 - ◆ pipes, and named pipes (FIFOs)
 - ◆ sockets
 - ◆ messages and message queues
 - ◆ shared memory regions
- All have some overhead

[IPC — Signals](#)

[Signals and the Shell](#)

[Threads](#)

[Race Condition](#)

[Summary and References](#)

Interprocess Communication (IPC)

- **Pipe** — circular buffer, can be written by one process, read by another
 - ◆ related processes can use unnamed pipes
 - used in **shell programming**, e.g., the vertical bar '|' in
\$ **find /etc | xargs file**
 - ◆ unrelated processes can use **named pipes** — sometimes called **FIFOs**
- **Messages** — POSIX provides system calls `msgsnd()` and `msgrcv()`
 - ◆ message is block of text with a type
 - ◆ each process has a message queue, like a mailbox
 - ◆ processes are suspended when attempt to read from empty queue, or write to full queue.

\(IPC\)](#)

[IPC — Shared Memory](#)

[IPC — Signals](#)

[Signals and the Shell](#)

[Threads](#)

[Race Condition](#)

[Summary and References](#)

IPC — Signals

- Some *signals* can be generated from the keyboard, i.e., **Control-C** — interrupt (`SIGINT`); **Control-** — quit (`SIGQUIT`), **Control-Z** — stop (`SIGSTOP`)
- A process **sends a signal** to another process using the `kill()` system call
- signals are implemented as single bits in a field in the PCB, so cannot be queued
- A process may respond to a signal with:
 - ◆ a *default action* (usually process terminates)
 - ◆ a *signal handler* function (see `trap` in shell programming notes), or
 - ◆ ignore the signal (unless it is `SIGKILL` or `SIGSTOP`)
- A process *cannot ignore*, or handle a `SIGSTOP` or a `SIGKILL` signal.
 - ◆ A `KILL` signal will *always terminate* a process (unless it is in interruptible sleep)
 - ◆ A `SIGSTOP` signal will *always* send a process into the stopped state.

Race Condition

Summary and References

Signals and the Shell

- We can use the **kill** built in command to make the **kill()** system call to *send* a signal
- A shell script uses the **trap** built in command to *handle* a signal
- *Ignoring* the signals SIGINT, SIGQUIT and SIGTERM:

```
trap "" INT QUIT TERM
```
- *Handling* the same signals by printing a message then exiting:

```
trap "echo 'Got a signal; exiting.';exit 1" INT QUIT TERM
```
- Handling the same signals with a function call:

```
signal_handler() {  
    echo "Received a signal; terminating."  
    rm -f $temp_file  
    exit 1  
}  
trap signal_handler INT QUIT TERM
```
- *Sending* a SIGKILL signal to process with PID 3233:

```
$ kill -KILL 3233
```

[Problem with threads:](#)

[Race Condition](#)

[Summary and References](#)

Threads and Processes

- Threads in a process all share the same address space
- Communication easier
- Overhead less
- Problems of *locking* and *deadlock* a major issue
- Processes have separate address spaces
- Communication more indirect: IPC (Inter Process Communication)
- Overhead higher
- Less problem with shared resources (since fewer resources to share!)

[Threads share a lot](#)

[Problem with threads:](#)

[Race Condition](#)

[Summary and References](#)

Threads share a lot

- Changes made by one thread to shared system resources (such as closing a file) will be seen by all other threads.
- Two pointers having the same value point to the same data.
- A number of threads can read and write to the same memory locations, and so you need to explicitly *synchronise* access

[Threads and Processes](#)

[Threads have own...](#)

[Threads share a lot](#)

[Problem with threads:](#)

[Race Condition](#)

[Summary and References](#)

Problem with threads:

- Avoid 2 or more threads writing or reading and writing same data at the same time
- Avoid *data corruption*
- Need to control access to data, devices, files
- Need *locking*
- Provide three methods of locking:
 - ◆ mutex (**mutual exclusion**)
 - ◆ semaphores
 - ◆ condition variables

[Summary and References](#)

Race Conditions

- *race condition* — where outcome of computation depends on scheduling
- an error in coding
- Example: two threads both access same list with code like this:

```
if ( list.numitems > 0 ) {  
    // Oh, dear, better not change to  
    // other thread here!  
    remove_item( list ); // not here!  
    // ...and not here either:  
    --list.numitems;  
}
```

[Solution: Synchronisation](#)

[File Locking](#)

[Summary and References](#)

Critical Sections

- *critical resource* — a device, file or piece of data that cannot be shared
- *critical section* — part of program only one thread or process should access **contains a critical resource**
 - ◆ i.e., you lock *data*, *not code*
- All the code in the previous slide is a critical section
- Consider the code:

```
very_important_count++;
```
- executed by two threads on a multiprocessor machine (SMP = **s**ymmetric **m**ultiprocessor)

[Solution: Synchronisation](#)

[File Locking](#)

[Summary and References](#)

Solution: Synchronisation

- Solution is to recognise *critical sections*
- use *synchronisation*, i.e., locking, to make sure only one thread or process can enter critical region at one time.
- Methods of synchronisation include:
 - ◆ file locking
 - ◆ semaphores
 - ◆ monitors
 - ◆ spinlocks
 - ◆ mutexes

[Solution: Synchronisation](#)

[File Locking](#)

[Summary and References](#)

File Locking

- For example, an `fcntl()` system call can be used to provide *exclusive access* to an open file
- The call is *atomic*
 - ◆ It either:
 - completely succeeds in locking access to the file, or
 - it fails to lock access to the file, because another thread or process holds the lock
 - No “half-locked” state
 - ◆ *No race condition*
- Alternatives can result in race conditions; for example:
 - ◆ thread/process 1 checks lockfile
 - ◆ thread/process 2 checks lockfile a very short time later
 - ◆ both processes think they have exclusive write access to the file
 - ◆ file is corrupted by two threads/processes writing to it at the same time
