Goals of SNMPv3 (RFC 3411)

- Avoid reinventing the wheel—use existing work
- Support secure `set` operation
- Support forward and backward compatibility
- Support remote configuration
 - ◆ USM and VACM configuration is through SNMP tables and variables
- **Security** protection against:
 - ◆ modification of information by unauthorised parties
 - ◆ an unauthorised person masquerading as an authorised person
 - ◆ message stream modification by reordering, delaying or replaying exchanges
 - ◆ disclosure (eavesdropping)

Goals of SNMPv3 (RFC 3411)

VACM Examples

User-based Security Model

References

- The *View-based Access Control Model* (*VACM*)
- VACM has five main components, as we mentioned earlier:
 - ◆ *groups* of users
 - ◆ *security level*, i.e., v1, v2c, usm
 - ◆ *contexts* — see slide §4
 - ◆ *MIB views, view families* — see slide §15
 - ◆ *access policy*, i.e., read only, read-write, notify, no access.
- How do we set up SNMPv3 users on agents and network management software?
- How do we control access to a subset of MIB variables on an agent?

Goals of SNMPv3 (RFC 3411)

VACM Examples

User-based Security Model

References

- An SNMP *context* is a collection of management variables accessible by an SNMP entity.
- Gives a way to group variables into collections with different access policies.
- Example from RFC 3411: See slide §5
 - ◆ The engine uses the bridge MIB defined in RFC 1493
 - ◆ but the engine keeps management information for two separate bridges labeled `bridge1` and `bridge2`
 - ◆ Could be that neither bridge directly supports SNMP, so another device on the LAN collects data from the bridges using some other method
 - ◆ Makes this information available within the *context*

VACM on Net-SNMP

- Net-SNMP uses **four keywords** to set up VACM in `/etc/snmp/snmpd.conf`:
 - ◆ **com2sec**
 - ◆ **group**
 - ◆ **view**
 - ◆ **access**
- These set up access control to variables on the agent.
 - ◆ **access** and **view** determine *what* access is being controlled to.
 - ◆ **group** and **com2sec** determine *who* has this access.

User-based Security Model

References

access: Security Model, Security Level

- The parameter `<secmodel>` is the *Security Model*.
 - ◆ Can be one of: `any`, `v1`, `v2c` or `usm`.
 - ◆ Should be set to match the SNMP version of clients that will connect to this agent.
- Parameter `<seclvl>` *Security Level* tells whether we use authentication or encryption
 - ◆ Can be one of `noauth`, `auth`, or `priv`
 - ◆ Note that community strings are not counted as authentication, so for SNMPv1 and SNMPv2 we specify `noauth`
 - ◆ `priv` (privacy) means that we use both strong authentication *and* encryption.

access: The *<prefix>* Parameter

- The *<prefix>* parameter to `access` can be either `exact` or `prefix`.
- Indicates whether context name needs to match exactly or whether only the first part of the context name needs to match.
- The default value is `exact`.

Goals of SNMPv3 (RFC 3411)

VACM Examples

User-based Security Model

References

The com2sec keyword

- Maps a *community string* and a source IP or network address to a *security name* (user name).
- Syntax:
`com2sec <securityName> <source> <community>`
 - ◆ The security name is used by the `group` keyword — see §14
 - ◆ Source can be a hostname, a subnet or the word “default”
 - A subnet can be written as IP/mask or IP/BITS, e.g., our lab subnet can be written as 172.19.64.0/255.255.192.0 or 172.19.64.0/18.
- Only needed for access control with SNMPv1 and v2c
 - ◆ Not used with SNMPv3

The group Keyword

- maps pairs of *Security Model* and *Security Name* to a group name.
- Syntax:
`group <groupName> <securityModel> <securityName>`
- A Security Model is one of v1, v2c or usm.
- The *Security Name* is the *user name*.
- All members of one group have the same access rights.
- A user cannot belong to more than one group for each of the three security models.

References

Views and the `view` Keyword

- The view determines what part of the MIB access is controlled to.
- Uses concept of a *subtree*.
 - ◆ A *subtree* is a node in the MIB tree and all the elements under that node.
 - ◆ In other words, all the MIB elements in a subtree have the same common prefix.

■ Syntax:

```
view <viewName> <incl/excl> <subtree> <mask(optional)>
```

[View Mask](#)

[View Mask and the `ifTable`](#)

[VACM Examples](#)

[User-based Security Model](#)

[References](#)

The `view` Keyword — 2

- `<incl/excl>` can be either “included” or “excluded”
 - ◆ “included” means that the MIB view includes all the elements of the subtree;
 - ◆ “excluded” means that the MIB view excludes all the elements of the subtree.

[Goals of SNMPv3 \(RFC 3411\)](#)

Instance Number

- Notice that the index is the number at the end of the OID
- Called an *instance number*. Index starts from 1
- Suppose we are an ISP, want to allow customer A to view their own network interface, but not that of customer B, their competitor.
- Note that as we go along a row, the **OID element just before the instance number changes**
- Suppose customer A has a network interface with the index 5.

```
$ snmptranslate -On IF-MIB::ifOutOctets.5  
.1.3.6.1.2.1.2.2.1.16.5
```
- So want to allow access for customer A to

```
.1.3.6.1.2.1.2.2.1.*.5
```

The View Mask — 2

- We can provide a view mask to specify this:

- A *zero in the bit mask* is like a wildcard or “don’t care” specifier
- A mask of all 1’s is the same as a single view subtree specified by the family name (it’s the same as not specifying a mask)
- Here the mask is specified as ff.a0
- For Net-SNMP, the mask is specified as a list of hexadecimal *bytes* separated with ‘.’ or ‘:’.

The View Mask — 3

- Note that in creating a view mask, we start from the left, writing hexadecimal digits.
- We don't care about the bits representing non-existent elements after the end of the subtree parent.
 - ◆ I mean the bits to the right of the vertical line in slide §24
 - ◆ These bits could be one or zero; I chose zero, since zero means “don't care; you can use any value here”
- We can specify this *family of view subtrees* like this:
`view custA included interfaces.ifTable.ifEntry.ifIndex.5 ff.a0`
- This view can then be used in an `access` statement
 - ◆ see the example in slide §29

The View Mask — 4

- One bit in the view mask determines access to one element in the OID
 - ◆ It doesn't matter how big or small the numerical component of the OID is
 - ◆ one bit controls whether different values for that component are included in the family of view subtrees or not
- RFC 3415 says that any bit mask is extended with 1's to the same length in bits as the number of identifiers in the OID if it is shorter.
- As a consequence, a family mask of zero length corresponds to a single view subtree.

- Cisco IOS specifies a view with the following syntax:

```
snmp-server view viewA ifEntry.*.5 included
snmp-server view viewB ifEntry.*.2 included
```

- Can specify a group with:

```
snmp-server group groupA v3 auth read viewA
```

- Cisco uses the `snmp-server user` command to specify users and group membership

- See also pages 284–285 of *Essential SNMP*.

User-based Security Model

- USM allows remote configuration of users
- Securely supports strong authentication using MD5 or SHA1 and encryption using DES
- Remotely create new users by *cloning* existing users
- Can only clone a user once
- Each user **must be given access using VACM or that user account cannot be used**
 - ◆ Add the user to a *group*
 - ◆ provide *access* to that group through *views*

Configuring USM Users — 1

Configuring USM Users — 2

Remotely Creating USM Users

References

Configuring USM Users — 1

- USM users can be created with the `net-snmp-config` program:
- Stop the agent first, then create the initial user:

```
$ sudo service snmpd stop
$ sudo net-snmp-config --create-snmpv3-user \
  -a "my_password" myuser
```
- SNMPv3 pass phrases must be at least 8 characters long.
- We have created a user “myuser” with a password of “my_password” and using MD5 for authentication and DES for encryption.
- Very simple access control has been added to `/usr/share/snmp/snmpd.conf` allowing the user write access to entire tree

Configuring USM Users — 2

- Now start the agent, and test the user. First we test without encryption, then with encryption:

```
$ sudo service snmpd start
```

```
$ snmpget -v 3 -u myuser -l authNoPriv -a MD5 \  
-A my_password localhost sysUpTime.0
```

```
$ snmpget -v 3 -u myuser -l authPriv -a MD5 \  
-A my_password -x DES -X my_password localhost sysUpTime.0
```

- Can create as many users as you like in this way.
- Better to **improve access control** using VACM over the default of write access everywhere

Remotely Creating USM Users

- We clone the first user we created:

```
$ snmpusm -v 3 -u myuser -l authNoPriv -a MD5 \  
-A my_password localhost create nicku myuser
```

- We now have created user `nicku` with the same password as the “`myuser`” user.

- Now change the password:

```
$ snmpusm -v 3 -u nicku -l authNoPriv -a MD5 \  
-A my_password localhost passwd my_password \  
new_passphrase
```

- ◆ See `man snmpusm` and `man snmpcmd`

- Can put account information into a local

`~/ .snmp/snmp.conf` that is readable only by you

- ◆ See `man snmp.conf`
