# Description of Objective

## 1.114.1 Perform security administration tasks [4]

1.114.1  
Perform security  
administration tasks  
Weight 4

Nick Urbanik

Candidates should know how to review system configuration to ensure host security in accordance with local security policies. This objective includes how to configure TCP wrappers, find files with SUID/SGID bit set, verify packages, set or change user passwords and password aging information, update binaries as recommended by CERT, BUGTRAQ, and/or distribution's security alerts. Includes basic knowledge of ipchains and iptables.

# Rules for `hosts.allow`, `hosts.deny`

- ▶ Search stops at the first match *in this sequence*:
- ▶ Access will be granted when a (daemon,client) pair matches an entry in the `/etc/hosts.allow` file.
- ▶ Otherwise, access will be denied when a (daemon,client) pair matches an entry in the `/etc/hosts.deny` file.
- ▶ Otherwise, access will be granted.

# More about how tcp\_wrappers rules applied

- ▶ Because access rules in `hosts.allow` are applied first, they take precedence over rules specified in `hosts.deny`.
  - ▶ Therefore, if access to a service is allowed in `hosts.allow`, a rule denying access to that same service in `hosts.deny` is ignored.
- ▶ The rules in each file are read from the top down and the first matching rule for a given service is the only one applied. The *order of the rules is extremely important*.
- ▶ If no rules for the service are found in either file, or if neither file exists, access to the service is *granted*.
- ▶ changes to `hosts.allow` or `hosts.deny` *take effect immediately* without restarting network services.

# Example rule

```
vsftpd : .example.com
```

- ▶ watch for connections to the FTP daemon (`vsftpd`) from any host in the `example.com` domain.
- ▶ If this rule appears in `hosts.allow`, the connection is accepted.
- ▶ If this rule appears in `hosts.deny`, the connection is rejected.

# Wildcards

Wildcards allow TCP wrappers to more easily match groups of daemons or hosts. They are used most frequently in the client list field of access rules.

The following wildcards may be used:

**ALL** Matches everything. It can be used for both the daemon list and the client list.

**LOCAL** Matches any host that does not contain a period (.), such as `localhost`

**KNOWN** Matches any IP address which has a corresponding hostname; also matches usernames when the *ident* service is available (which is usually not)

**UNKNOWN** Matches any IP address which does *not* have a corresponding hostname; also matches usernames when the *ident* service *not* available

**PARANOID** Matches any host where a double reverse hostname/IP address lookup fails to match

# Patterns

- ▶ Hostname beginning with a period (.) This matches any host in the `example.com` domain:  
ALL : `.example.com`
- ▶ IP address ending with a period (.) This matches any host in the `192.168.x.x` network:  
ALL : `192.168.`
- ▶ IP address/netmask pair This matches any host in the address range `192.168.0.0 ... 192.168.1.255`:  
ALL : `192.168.0.0/255.255.254.0`
  - ▶ Note: a pattern of the form `192.168.0.0/23` *will not work*
- ▶ The asterisk (\*) Asterisks can match entire groups of hostnames or IP addresses. This matches any host in the `example.com` domain:  
ALL : `*.example.com`
  - ▶ This asterisk notation is not used anywhere else as far as I know.

- ▶ See `$ man 5 hosts_options` ← for details of other options; just look at `severity` directive for logging access
- ▶ Here, connections to the SSH daemon from any host in the `example.com` domain are logged to the default `authpriv` syslog facility (because no facility value is specified) with a level of `emerg`:  

```
sshd : .example.com : severity emerg
```
- ▶ specifying a facility: The following example logs any SSH connection attempts by hosts from the `example.com` domain to the `local0` facility with a level of `alert`:  

```
sshd : .example.com : severity  
local0.alert
```

# EXCEPT operator

- ▶ There is one operator: `EXCEPT`.
- ▶ can be used in both the daemon list and the client list of a rule.
- ▶ allows specific exceptions to broader matches within the same rule.
- ▶ Example:  

```
ALL: .example.com EXCEPT  
cracker.example.com
```
- ▶ In the another example from a `hosts.allow` file, clients from the `192.168.0.x` network can use all services except for FTP:  

```
ALL EXCEPT vsftpd: 192.168.0.
```

# How is TCP Wrappers enabled?

- ▶ Recent systems use `libwrap`, part of the `tcp_wrappers` package
- ▶ Red Hat suggest doing  
`$ strings -f <binary-name> | grep hosts_access` ←  
to see if a program is compiled with `libwrap`.
- ▶ Most programs are dynamically linked against `/usr/lib/libwrap.so.0`, so you can check for that with `$ ldd <binary-name>` ←
- ▶ Example:  

```
$ /usr/sbin/xinetd | grep libwrap ←  
libwrap.so.0 => /usr/lib/libwrap.so.0 (0x00320000)
```
- ▶ Older systems used `/usr/sbin/tcpd` and entered this in `/etc/inetd.conf` instead of the binary name of the service, but this is no longer necessary

# Effect of SUID/SGID permissions

- ▶ A *program* with Set User-ID (SUID) permission will execute with the process owned by the owner of the file instead of the user that executed the program.
- ▶ A *program* with Set Group-ID (SGID) permission will execute with the group of the process the same as the group of the file instead of the group of the user that executed the program.
- ▶ A serious security risk.

## Some History

- ▶ A friend in UNSW in 1985 used to stay in the lab with me till 5 AM many mornings; he had `root` access on the PDP-11, greatly upsetting the BOFH.
- ▶ He told me that he gained this through a set user-ID executable owned by `root`.

# Specifying Permissions to `find`

1.114.1  
Perform security  
administration tasks  
Weight 4

Nick Urbanik

- ▶ The `find` program finds files for which various conditions are true
- ▶ The `-perm <mode>` condition can find files which match the permissions specified in `<mode>` in various ways:
  - ▶ if `<mode>` starts with `'-'` then true if **all** of the permissions in `<mode>` are present. Any permissions not in `<mode>` are ignored
  - ▶ if `<mode>` starts with `'+'` then true if **any** of the permissions in `<mode>` are present. Any permissions not in `<mode>` are ignored
  - ▶ if `<mode>` starts with neither `'-'` nor `'+'` then true if permissions are exactly `<mode>`.
- ▶ `<mode>` can be specified in octal or symbolically: e.g., you can specify `-perm +6000` or `-perm +ug=s`
  - ▶ both are true if the file has either SUID or SGID permission set.

# Why Verify Software Packages?

Main reasons:

- ▶ As another tool to check whether trojan executables have been installed by a cracker, replacing the original binary
- ▶ As a check that software downloaded from the Internet is from a trusted source and has not been compromised

- ▶ Do `$ rpm -V <package-name>` ←
- ▶ Ensure that no binary executables have changed; here is an example of an executable that does not match the original installed version: `$ rpm -V spamassassin` ←  
`S.5....T /usr/bin/spamc`
- ▶ This indicates that the size, the MD5sum and the timestamp have changed of this executable file, and it could quite possibly be a trojan
- ▶ There are eight characters; a dot indicates original value, a letter shows there is change:

- S file **S**ize differs
- M **M**ode differs (includes permissions and file type)
- 5 MD**5** sum differs
- D **D**evice major/minor number mismatch
- L read**L**ink(2) path mismatch
- U **U**ser ownership differs
- G **G**roup ownership differs
- T m**T**ime differs

# Password Aging options to `passwd`

- d This is a quick way to disable a password for an account. It will set the named account passwordless. Available to root only.
- n This will set the minimum password lifetime, in days, if the user's account supports password lifetimes. Available to root only.
- x This will set the maximum password lifetime, in days, if the user's account supports password lifetimes. Available to root only.
- w This will set the number of days in advance the user will begin receiving warnings that her password will expire, if the user's account supports password lifetimes. Available to root only.
- i This will set the number of days which will pass before an expired password for this account will be taken to mean that the account is inactive and should be disabled, if the user's account supports password lifetimes. Available to root only.

Nick Urbanik

- ▶ You can either apply updates automatically: with systems with `yum` installed, enable `yum` updates in `cron`.
- ▶ To update a system with `yum`:  

```
$ sudo yum -y update ↵
```
- ▶ To update a system with `apt`:  

```
$ sudo apt-get update ↵  
$ sudo apt-get -y upgrade ↵
```
- ▶ If the system is mission critical and especially if it has complex software installed, install updates on a test system first

# What are iptables and ipchains?

1.114.1  
Perform security  
administration tasks  
Weight 4

Nick Urbanik

- ▶ Used to filter network packets coming into, out of and through the system
- ▶ Very useful for network security, Internet connection sharing
- ▶ `iptables` on 2.4, 2.6 kernels, `ipchains` on 2.2 kernels
- ▶ `iptables` is easier to use than `ipchains`
  - ▶ Many more things must be considered before you can predict what will happen to a packet passing through an `ipchains` system, while `iptables` tends to have a packet dealt with in one spot only, causing less brain pain.
- ▶ `iptables` has support for *stateful inspection* which allows the system to remember which response is in answer to which packet

# Components of iptables

1.114.1  
Perform security  
administration tasks  
Weight 4

Nick Urbanik

- There are four main terms to consider with iptables:
  - table** — a table holds a major category of set of rules.
  - chain** — sets of rules within a table that affect traffic
  - rule** — decides how to send a packet to a *target*.  
Next rule checks a packet if this doesn't match.
  - target** — can be ACCEPT, DROP, QUEUE, or RETURN. A matched packet is accepted, dropped, queued on another chain or returned to the parent chain from the current chain.

# iptables tables

- ▶ There are three *tables* used by `iptables`:
  - `filter` — default table for handling network packets
  - `nat` — used to alter packets that create a new connection and used for Network Address Translation (NAT).
  - `mangle` — for specific types of packet alteration, including time to live, type of service — for special routing purposes

1.114.1

Perform security  
administration tasks  
Weight 4

Nick Urbanik

Context

Objectives

Configuring TCP  
Wrappers

Finding files with  
SUID/SGID bit set

Verify Packages

Passwords and Aging  
Information

Update binaries with  
security alerts

Basic intro to  
iptables and  
ipchains

References

License Of This  
Document

# Topics Covered

## Context

## Objectives

## Configuring TCP Wrappers

Rules for `hosts.allow`, `hosts.deny`

Format of rules in `hosts.{allow,deny}`

Example

Wildcards

Patterns

Option Fields: Logging

`EXCEPT` operator

How is TCP Wrappers enabled?

## Finding files with SUID/SGID bit set

Effect of SUID/SGID permissions

Specifying Permissions to `find`

Finding SUID or SGID files

## Verify Packages

Why Verify Software Packages?

Verify Package Files with `rpm`

Verify Installed Packages with `rpm`

Verify Packages with `apt/dpkg`

## Passwords and Aging Information
